Microprocessor Systems

Xie Ming, PhD (France)

mmxie@ntu.edu.sg

<http://personal.ntu.edu.sg/mmxie>

Outline

- ▶ Lecture 1: Basics of ARM Microcontroller
- ▶ Lecture 2: ARM's Memories
- ▶ Lecture 3: ARM's Data Representation
- ▶ Lecture 4: ARM's Programming
- ▶ Lecture 5: ARM's Data Input/Output
- ▶ Lecture 6: ARM's Data Processing

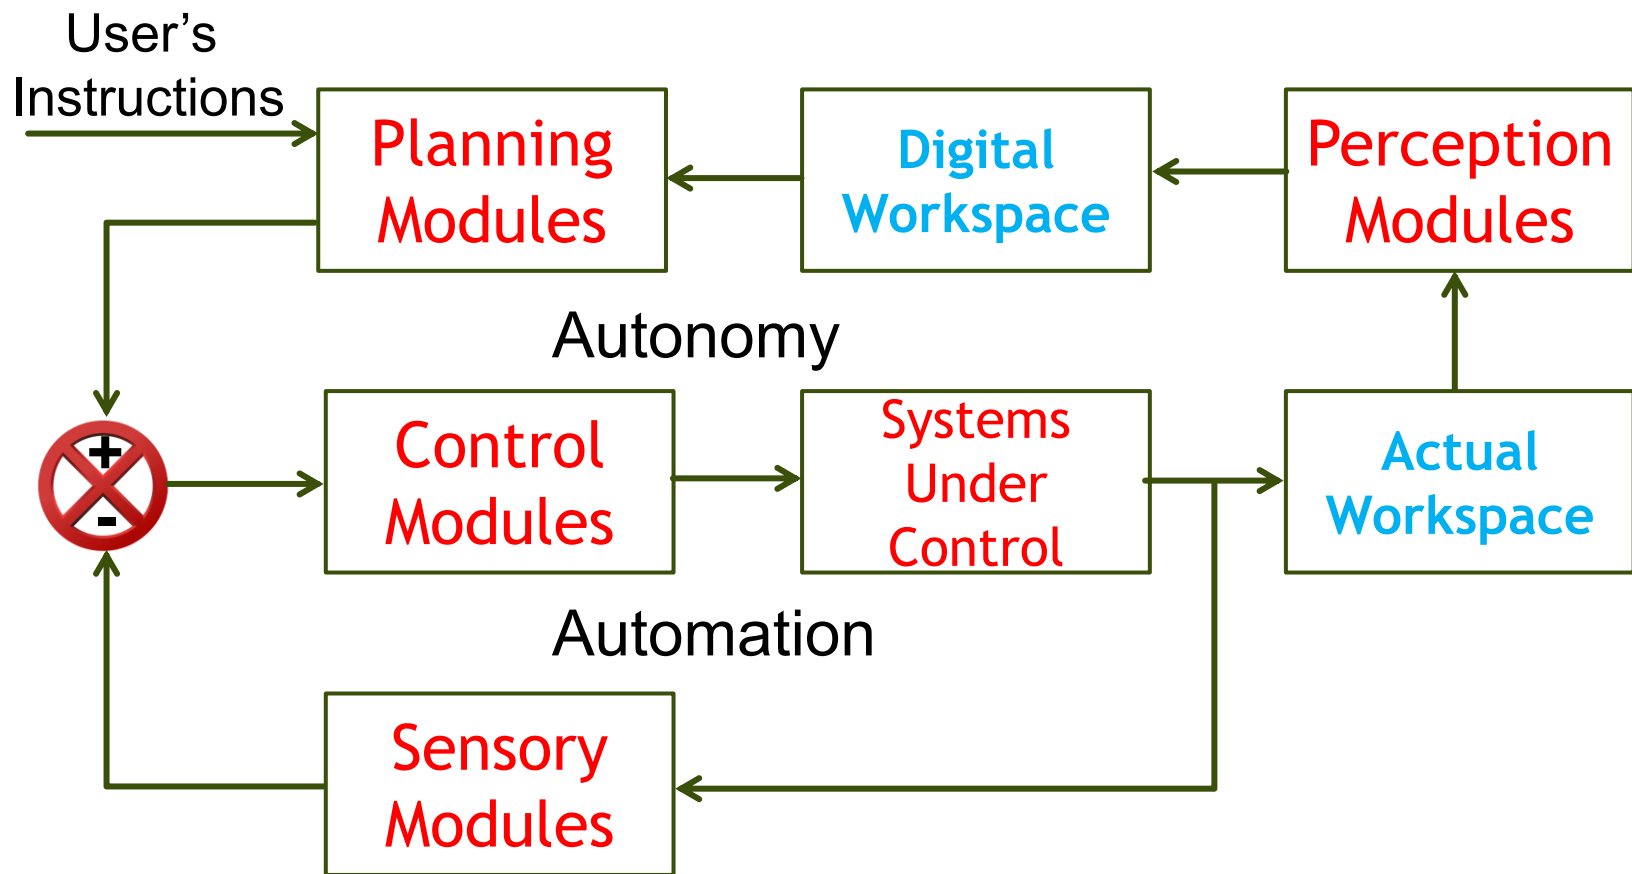

Block diagram of Computer with sub-units of CPU

Remember your mission as MAE undergraduates ...

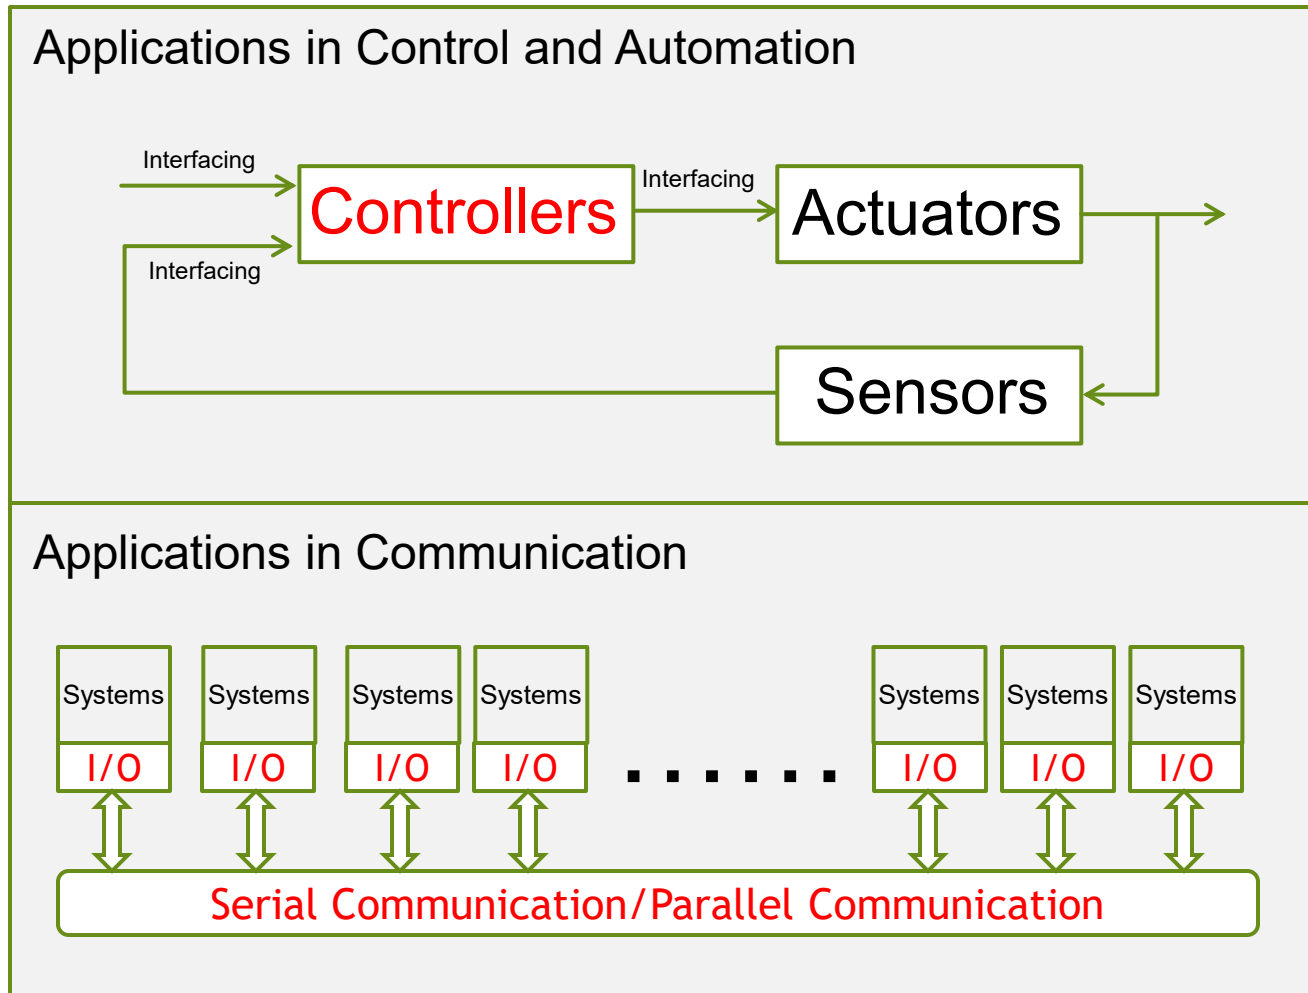

- ▶ You are here to grow your knowledge and skills so as to be able to design machines with **controllable behaviors** and hopefully in some **intelligent ways**.

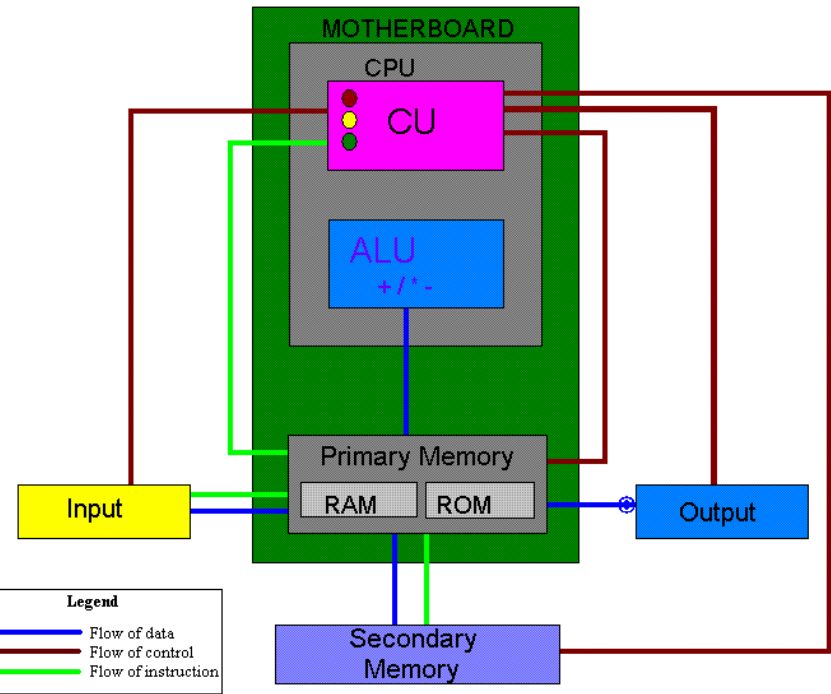

How to fulfill your mission?

- ▶ To apply learnt knowledge and skills into the implementation of the following universal blueprint underlying all the intelligent machines or systems.

Why to study?

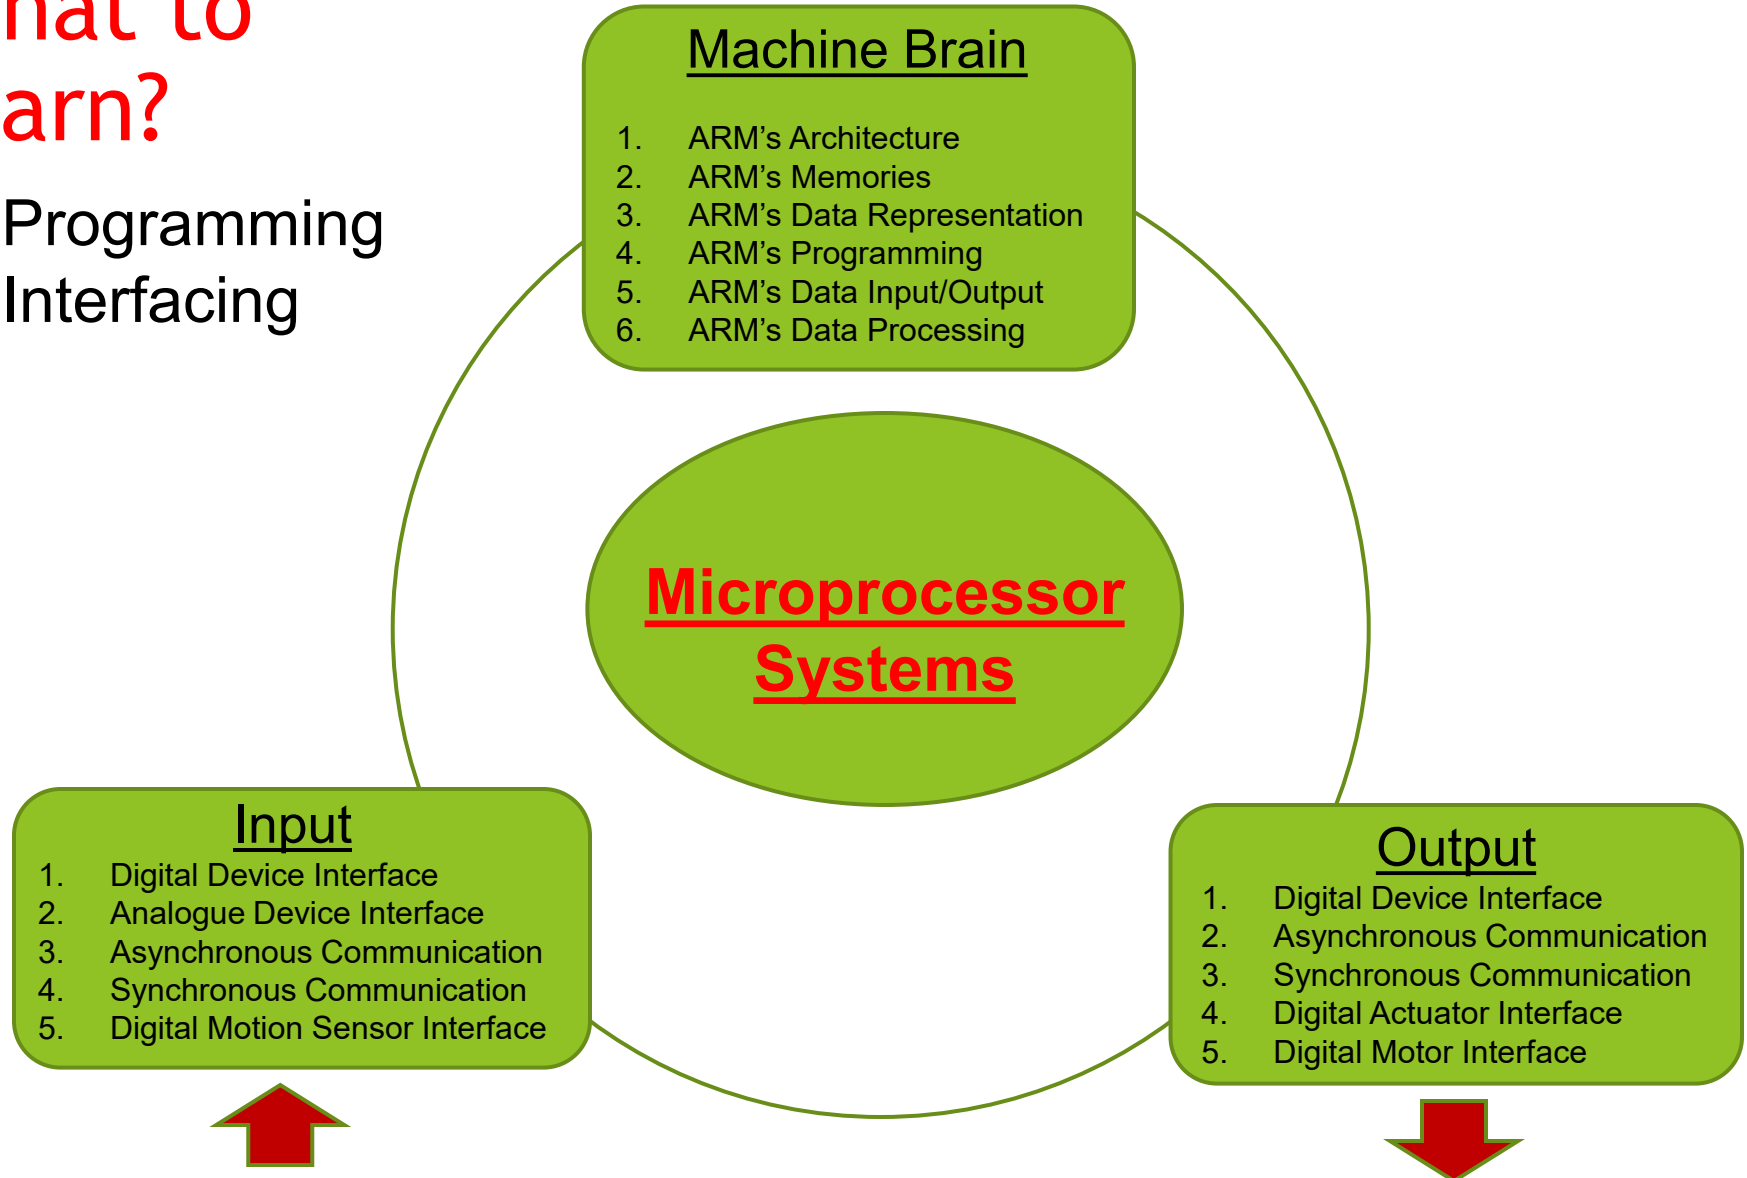

Block diagram of Computer with sub-units of CPU

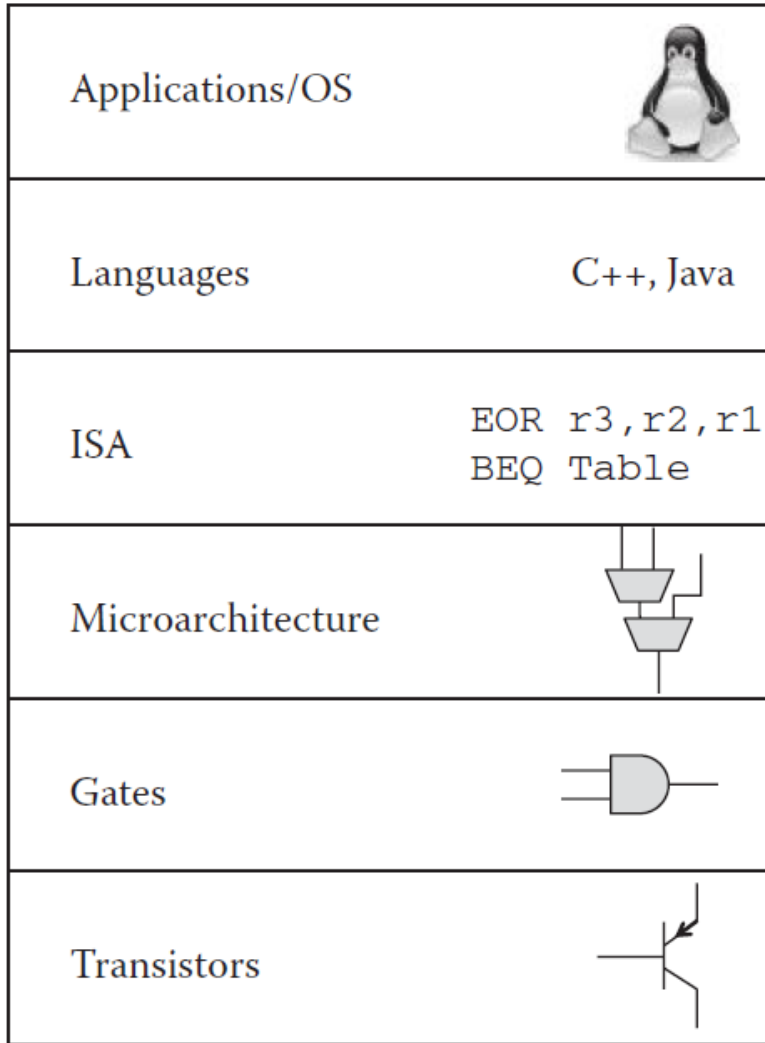

What to learn?

- Programming
- Interfacing

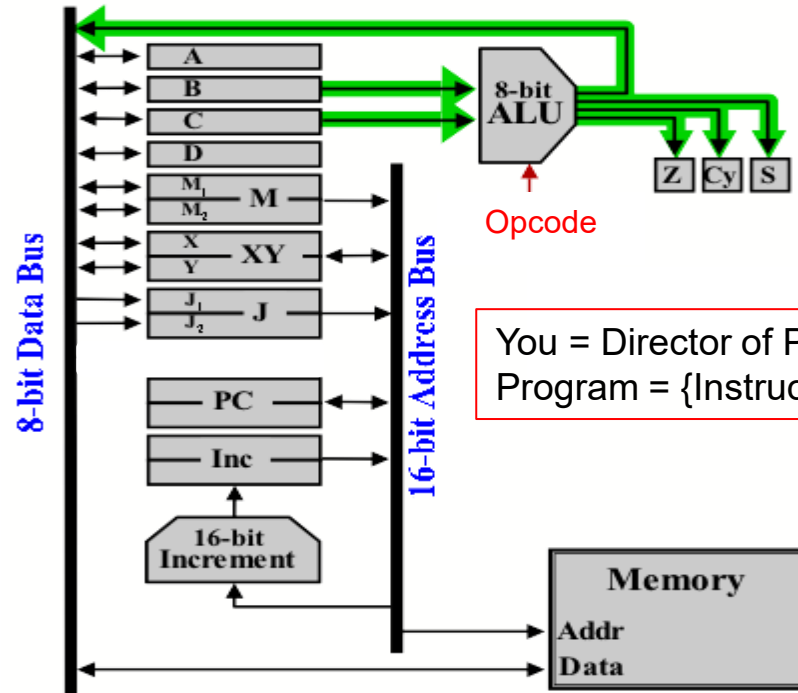

What is your role?

- Data = {Values, Symbols, Addresses, Instructions}
- Instructions = {Op Code + Addresses + Value/Symbol}

Algorithms or Solutions

Problems to be solved

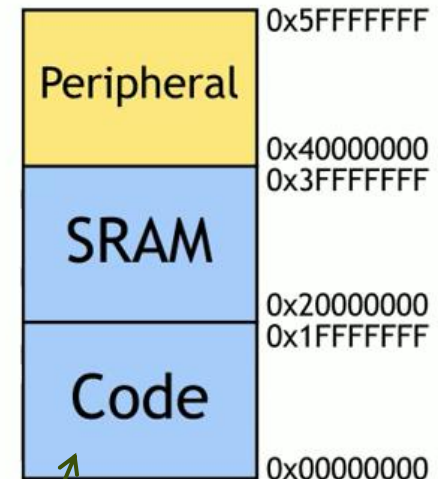

You = Director of Program
Program = {Instructions}

Memory = {Address + Data/Instruction}

How to learn?

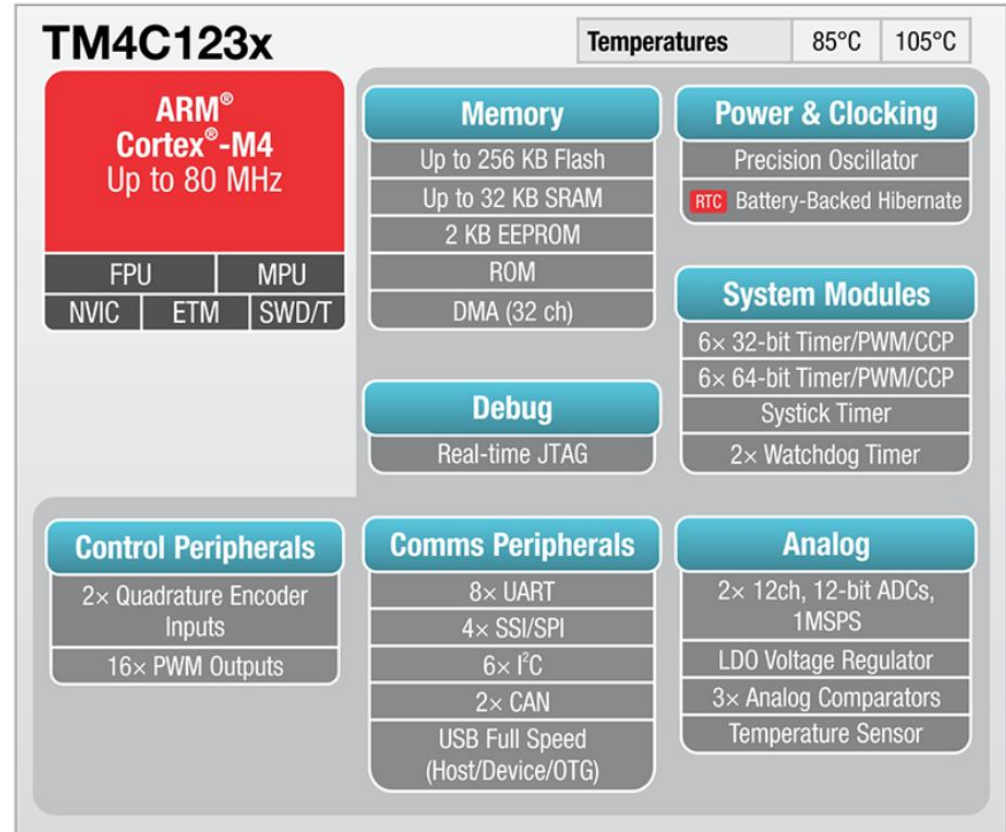

- ▶ To **understand** data flows inside a microcontroller.
- ▶ To **translate** your solutions into data flows.
- ▶ To pay attention to <memory address> and <memory data>.
 - ▶ Memory Address: Address Label/Name and Address Value.
 - ▶ Memory Data: Data Label/Name and Data Value.
- ▶ To pay attention to <memory address> and <memory code>.
 - ▶ Memory Address: Address Label/Name and Address Value.
 - ▶ Memory Code: Code Label/Name and Code Value.

Series of Instructions

Example of Using I/O Modules

- ▶ Configure **Control** Registers
- ▶ Clear/Monitor **Status** Registers
- ▶ Read/Write **Data** Registers
- ▶ Instructions:

- ▶ MOV <address of destination>, <source of value>
- ▶ LDR <address of destination>, <source of value>
- ▶ STR <source of value>, <address of destination>

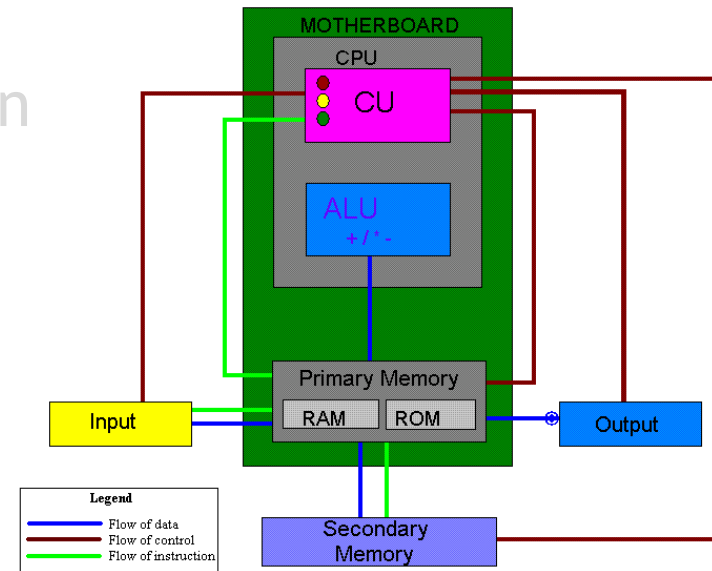

```

MOV R0, #0x11
MOV R1, #2560
MVN R2, #4
MOVW R3, #0xC0DE
MOVT R3, #0xFEED
MOV R4, R1
    
```

Word = 2 Bytes

Today's Lecture ...

- ▶ Lecture 1: Basics of ARM Microcontroller
- ▶ Lecture 2: ARM's Memories
- ▶ Lecture 3: ARM's Data Representation
- ▶ **Lecture 4: ARM's Programming**
- ▶ Lecture 5: ARM's Data Input/Output
- ▶ Lecture 6: ARM's Data Processing

Block diagram of Computer with sub-units of CPU

ARM's Programming

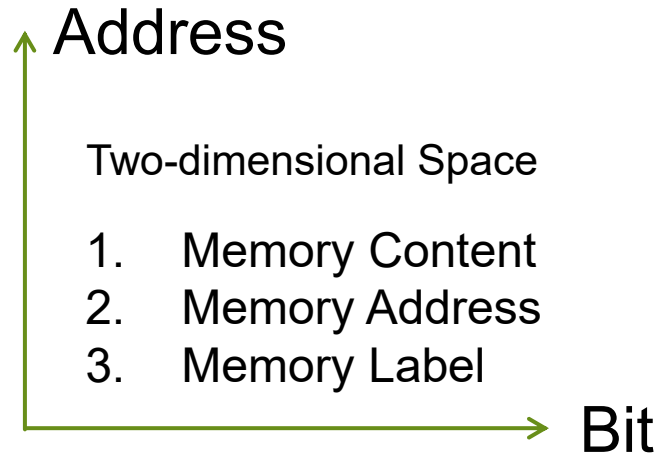

Xie Ming, PhD (France)

<http://personal.ntu.edu.sg/mmxie>

Outline

You = Director of Program
 Program = {Instructions}

- ▶ Nature of Programming
- ▶ Planning of Computations in Programming
- ▶ Allocation of Memory in Programming
- ▶ ARM Programming Tools

Outline

You = Director of Program
 Program = {Instructions}

- ▶ Nature of Programming
- ▶ Planning of Computations in Programming
- ▶ Allocation of Memory in Programming
- ▶ ARM Programming Tools

Programming versus Writing

Programming

Use of Programming Languages?

- ▶ You have a solution in mind
- ▶ You organize your solution
- ▶ You **compose** your program
- ▶ You test your program
- ▶ You deploy your program

Use of Keil

Writing

Use of Natural Languages?

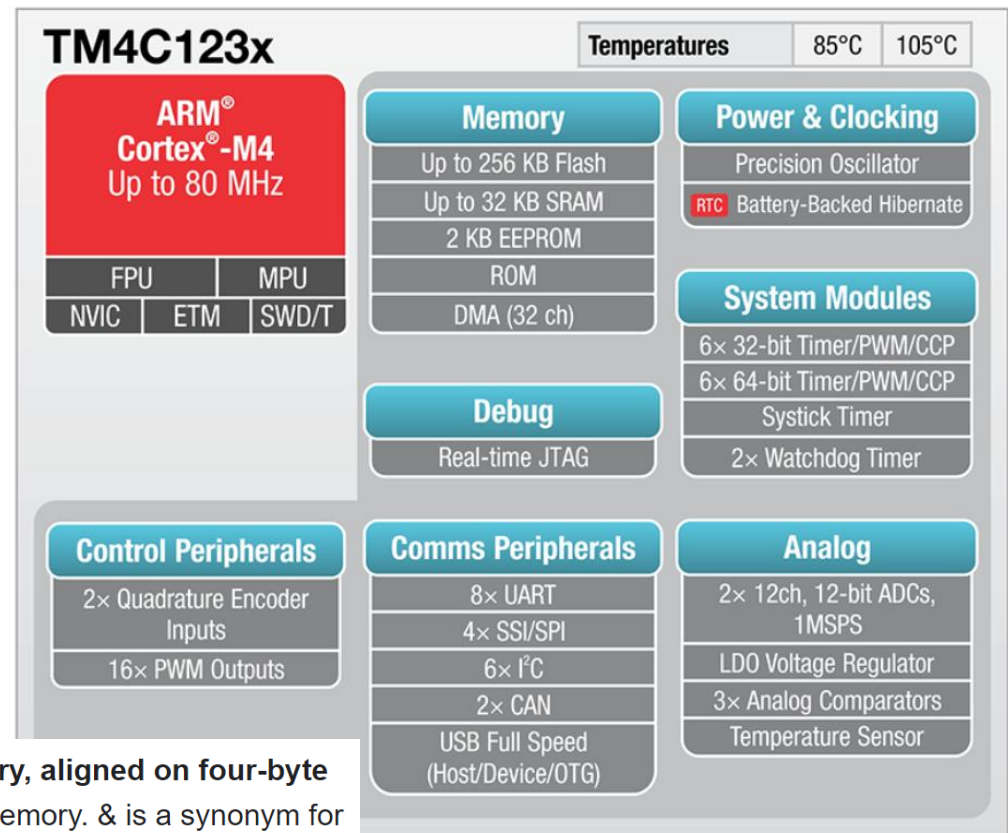

- ▶ You have a story in mind
- ▶ You organize your story
- ▶ You **compose** your texts
- ▶ You proof-read your texts
- ▶ You publish your texts

Use of LaTeX, Word

How to organize your solution?

FPU: Floating-Point Unit
MPU: Multi-core Processing Unit

- ▶ Step 1: To plan arithmetic and/or logical computations underlying your solution
- ▶ Step 2: To allocate memory resources which are indispensable for the implementation of the planned computations.

The DCD **directive allocates one or more words of memory, aligned on four-byte boundaries**, and defines the initial runtime contents of the memory. & is a synonym for DCD . DCUDU is the same, except that the memory alignment is arbitrary.

Example of doing $x = (a + b) - c$

		EXPORT Start		
		AREA progA, CODE, READONLY		
	var_a	DCD 5	; a = 5	4 byte words
	var_b	DCD 6	; b = 6	
	var_c	DCD 7	; c = 7	
	var_x	DCD 0	; x = 4	
				Allocation of Memory
			; x = (a + b) - c	
Start		ADR r4,var_a	; get address for a	
		LDR r0,[r4]	; get value of a	
		ADR r4,var_b	; get address for b, reusing r4	
		LDR r1,[r4]	; get value of b	
		ADD r3,r0,r1	; compute a + b	
		ADR r4,var_c	; get address for c	
		LDR r2,[r4]	; get value of c	
		SUB r3,r3,r2	; complete computation of x	
		ADR r4,var_x	; get address for x	
		STR r3,[r4]	; store value of x	
				Planning of Computations
stop	B	stop		
		END		

ADR loads address to a register

Role of Programmers: Planning and Allocation

- Data = {Values, Symbols, Addresses, Instructions}
- Instructions = {Op Code + Addresses + Value/Symbol}

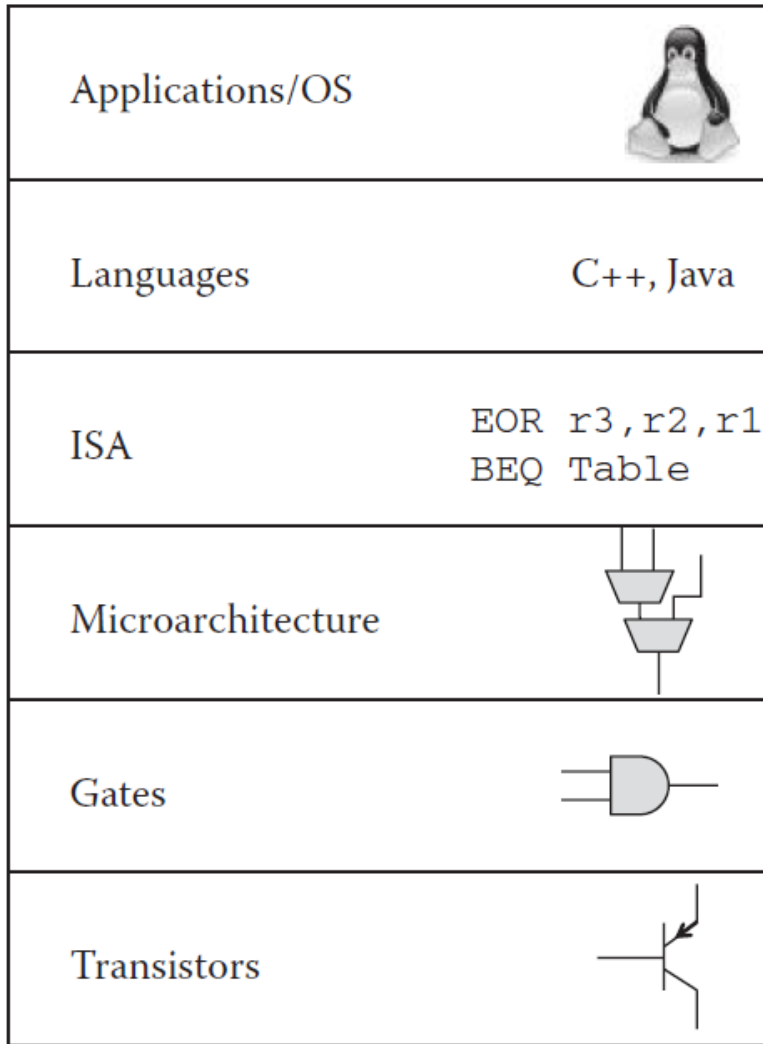

You = Director of Program
Program = {Instructions}

Memory = {Address + Data/Instruction}

Role of Microprocessors: Do Cycle-by-Cycle Executions

- Data = {Values, Symbols, Addresses, Instructions}
- Instructions = {Op Code + Addresses + Value/Symbol}

Problems to be solved

Algorithms or Solutions

You = Director of Program
Program = {Instructions}

Memory = {Address + Data/Instruction}

Outline

You = Director of Program
 Program = {Instructions}

- ▶ Nature of Programming
- ▶ Planning of Computations in Programming
- ▶ Allocation of Memory in Programming
- ▶ ARM Programming Tools

Procedure of Planning Computations

- ▶ Step 1: Describe your solution in the form of mathematics or logics.
- ▶ Step 2: Transform your solution into algorithms which consist of series of arithmetic and/or logical computations.
- ▶ Step 3: Draw flowcharts which interconnect arithmetic and/or logical computations in terms of their inputs and outputs.
- ▶ Step 4: Describe flowcharts with the use of a programming language.

Example of Transforming Solution into Algorithm

Solution:

$$ax^2 + bx + c = 0$$

$$x_1 = \frac{-b + \sqrt{b^2 - 4ac}}{2a}$$

$$x_2 = \frac{-b - \sqrt{b^2 - 4ac}}{2a}$$

Algorithm:

First do: $y = b^2 - 4ac$

Then do: $z = \sqrt{y}$

Then do: $x_1 = \frac{-b + z}{2a}$

Then do: $x_2 = \frac{-b - z}{2a}$

Example of Flowchart Corresponding to Algorithm

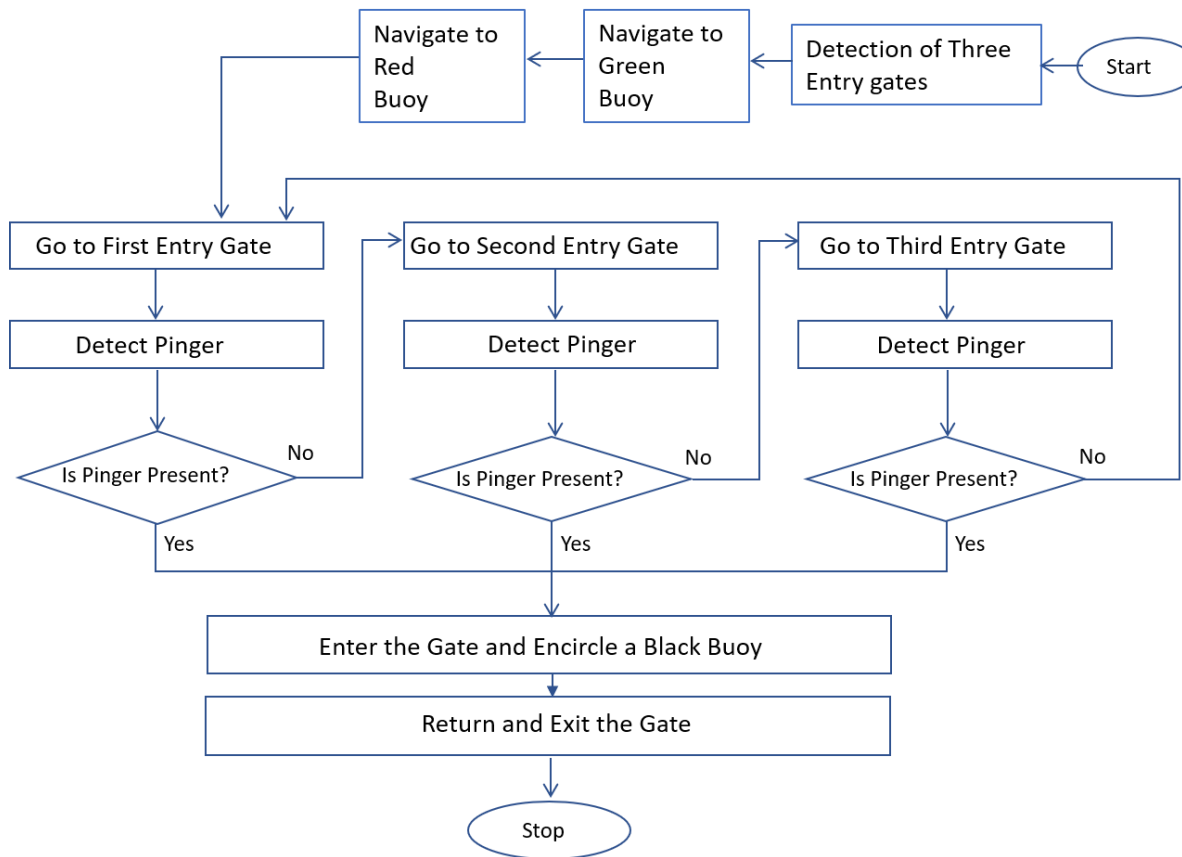

Example of Translation Flowchart into a Sequence of Instructions ...

Burger Shop

```
void setup() {  
  cleanTheShop()  
  prepareIngredient()  
  openTheStore()  
}  
void loop() {  
  welcomeCustomer()  
  receiveOrder()  
  makeFood()  
  deliverFood()  
}
```

More Example of Flowchart Corresponding to Algorithm

Outline

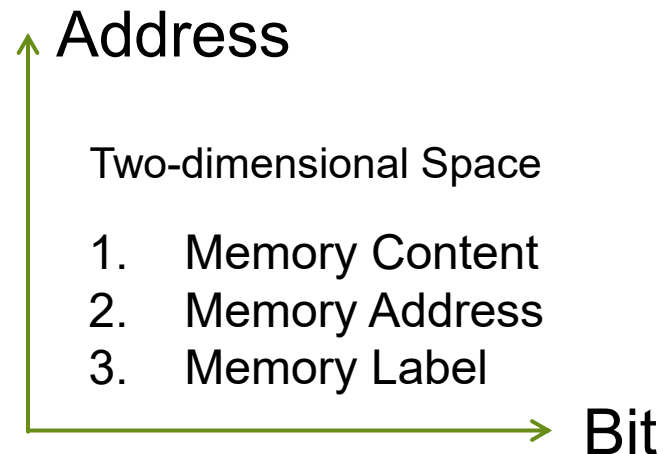

You = Director of Program
Program = {Instructions}

- ▶ Nature of Programming
- ▶ Planning of Computations in Programming
- ▶ Allocation of Memory in Programming
- ▶ ARM Programming Tools

Motivation

- ▶ The hardware could support the concurrent running of multiple application programs.
- ▶ The ALU is being shared among these programs. This means that an application program has the full access to the ALU during the time when ALU is allocated to it.
- ▶ However, memory units are not shared in general.
- ▶ Hence, each application program must take care of memory allocation explicitly.

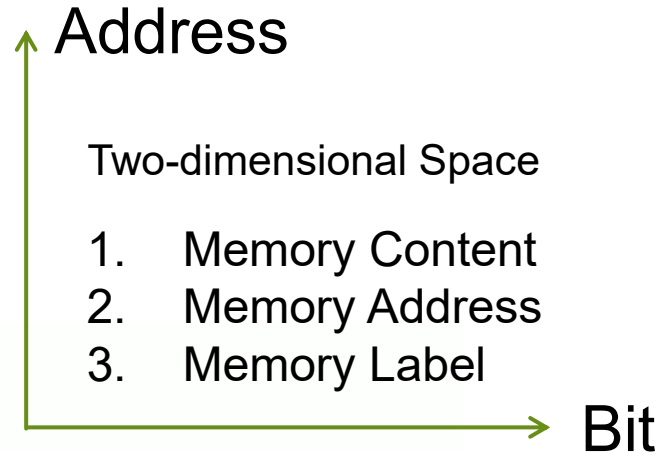

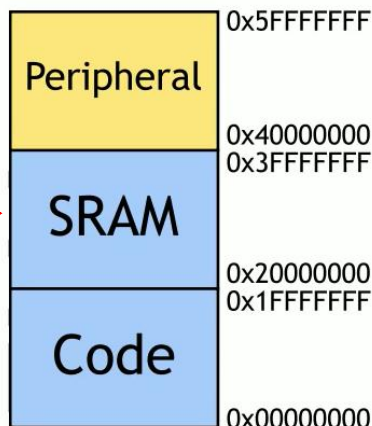

ALU is shared while memory is to be reserved

Scenario of Memory Allocation

- ▶ Scenario 1: Allocation of memory for housing a program itself.
- ▶ Scenario 2: Allocation of memory for housing constants, parameters and variables of a program.

Cortex-M Memory
On-chip Memory Space

GiB = Giga Byte

- ▶ On-chip code, data, and I/O are located in the first 1.5 GiB of memory space
- ▶ Each is allocated 0.5 GiB
- ▶ May use physically separate buses for each space

mem32[address]: consider the memory as a vector

Example of Memory Allocation

```

EXPORT Start
AREA progB, CODE, READONLY
var_a DCD 1 ; a = 1 (DCD creates 4 byte variables)
var_b DCD 15 ; b = 15
var_z DCD 0 ; z = 5

```

Start

```

ADR r4, var_a ; get address for a
LDR r0, [r4] ; get value of a
MOV r0, r0, LSL #2 ; perform shift → r0 = (a<<2)
ADR r4, var_b ; get address for b
LDR r1, [r4] ; get value of b
AND r1, r1, #15 ; perform AND → r1 = (b & 152)
ORR r1, r0, r1 ; perform OR → r1 = (a<<2) | (b & 152)
ADR r4, var_z ; get address for z
STR r1, [r4] ; store value for z

```

stop

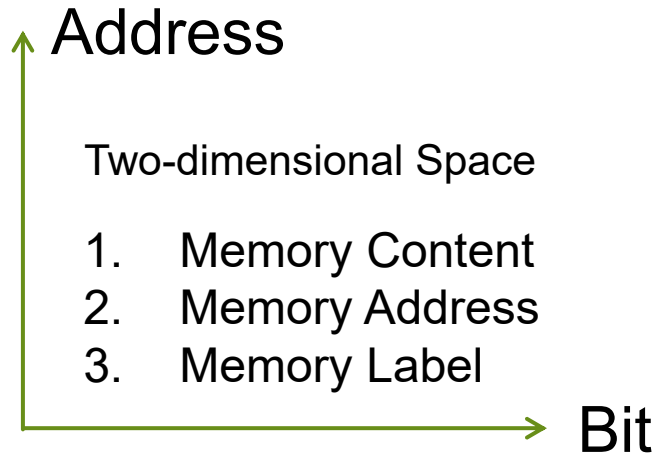

```

B stop
END

```

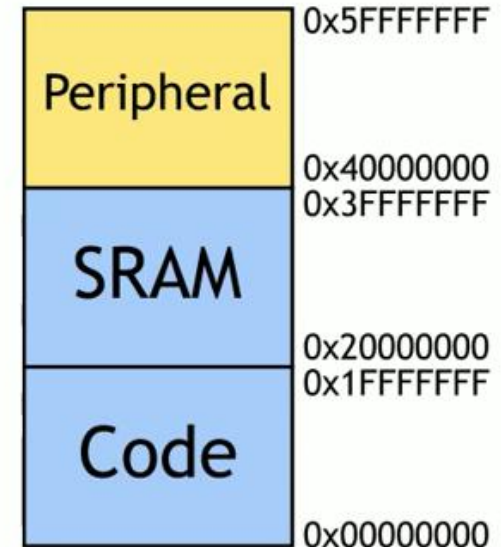

mem32[address]: consider the memory as a vector

- ▶ ARM Programming Tools

Overview

- ▶ **Compiler:**
 - ▶ From .c files to .s files

- ▶ **Assembler:**
 - ▶ From .s files to .o files
- ▶ **Linker:**
 - ▶ From .o files to .exe files
 - ▶ May be linked with .a files

Assembler Directives for Memory Destination

Mnemonic and Syntax	Description
.bss <i>symbol, size in bytes[, alignment [, bank offset]]</i>	Reserves <i>size</i> bytes in the .bss (uninitialized data) section
.data	Assembles into the .data (initialized data) section
.sect " <i>section name</i> "	Assembles into a named (initialized) section
.text	Assembles into the .text (executable code) section
<i>symbol</i> .usect " <i>section name</i> ", <i>size in bytes [, alignment[, bank offset]]</i>	Reserves <i>size</i> bytes in a named (uninitialized) section

Cortex-M Memory

On-chip Memory Space

SRAM: Data Only
CODE: Instructions/Data

- Short-term memory
- Working memory

Examples

.space reserves a block of bytes

In this example, code is assembled into the .data and .text sections.

Machine Readable	<pre> 1 2 3 4 00000000 5 00000000 6 7 8 9 10 00000000 11 00000000 12 00000000 E3A00000 13 14 15 16 17 000000cc 18 000000cc FFFFFFFF 19 20 21 000000d0 FF 22 23 24 25 26 27 00000004 28 00000004 000000CC 29 00000008 E51F100C 30 0000000c E5912000 31 00000010 E0802002 </pre>	<pre> ***** ** Reserve space in .data. ** ***** .data .space 0CCh ***** ** Assemble into .text. ** ***** .text ; Constant into .data INDEX .set 0 MOV R0, #INDEX ***** ** Assemble into .data. ** ***** Table: .data .word -1 ; Assemble 32-bit ; constant into .data. .byte 0FFh ; Assemble 8-bit ; constant into .data. ***** ** Assemble into .text. ** ***** .text con: .field Table, 32 LDR R1, con LDR R2, [R1] ADD R2, R0, R2 </pre>	Human Readable
------------------	--	--	----------------

Assembler Directives for Data's Memory Allocation

Mnemonic and Syntax	Description
.cstring { <i>expr</i> ₁ "string ₁ "}, ..., { <i>expr</i> _{<i>n</i>} "string _{<i>n</i>} "}	Initializes one or more text strings
.double <i>value</i> ₁ [, ... , <i>value</i> _{<i>n</i>}]	Initializes one or more 64-bit, IEEE double-precision, floating-point constants
.field <i>value</i> [, <i>size</i>]	Initializes a field of <i>size</i> bits (1-32) with <i>value</i>
.float <i>value</i> ₁ [, ... , <i>value</i> _{<i>n</i>}]	Initializes one or more 32-bit, IEEE single-precision, floating-point constants
.half <i>value</i> ₁ [, ... , <i>value</i> _{<i>n</i>}]	Initializes one or more 16-bit integers (halfword)
.int <i>value</i> ₁ [, ... , <i>value</i> _{<i>n</i>}]	Initializes one or more 32-bit integers
.long <i>value</i> ₁ [, ... , <i>value</i> _{<i>n</i>}]	Initializes one or more 32-bit integers
.short <i>value</i> ₁ [, ... , <i>value</i> _{<i>n</i>}]	Initializes one or more 16-bit integers (halfword)
.string { <i>expr</i> ₁ "string ₁ "}, ..., { <i>expr</i> _{<i>n</i>} "string _{<i>n</i>} "}	Initializes one or more text strings
.ubyte <i>value</i> ₁ [, ... , <i>value</i> _{<i>n</i>}]	Initializes one or more successive unsigned bytes in the current section
.uchar <i>value</i> ₁ [, ... , <i>value</i> _{<i>n</i>}]	Initializes one or more successive unsigned bytes in the current section
.uhalf <i>value</i> ₁ [, ... , <i>value</i> _{<i>n</i>}]	Initializes one or more unsigned 16-bit integers (halfword)
.uint <i>value</i> ₁ [, ... , <i>value</i> _{<i>n</i>}]	Initializes one or more unsigned 32-bit integers
.ulong <i>value</i> ₁ [, ... , <i>value</i> _{<i>n</i>}]	Initializes one or more unsigned 32-bit integers
.ushort <i>value</i> ₁ [, ... , <i>value</i> _{<i>n</i>}]	Initializes one or more unsigned 16-bit integers (halfword)
.uword <i>value</i> ₁ [, ... , <i>value</i> _{<i>n</i>}]	Initializes one or more unsigned 32-bit integers
.word <i>value</i> ₁ [, ... , <i>value</i> _{<i>n</i>}]	Initializes one or more 32-bit integers

Examples

Example 1

This example uses the `.int` directive to initialize words.

```

1 00000000          |          .space 73h
2 00000000          |          .bss   PAGE, 128   ; Reserve 128 bytes for pointer PAGE
3 00000080          |          .bss   SYMPTR, 4   ; Reserve 4 bytes for pointer SYMPTR
4 00000074 E3A00056 | INST:  MOV    R0, #056h
5 00000078 0000000A |          .int   10, SYMPTR, -1, 35 + 'a', INST, "abc"
   0000007c 00000080 |
   00000080 FFFFFFFF |
   00000084 00000084 |
   00000088 00000074 |
   0000008c 00000061 |
   00000090 00000062 |
   00000094 00000063 |

```

Example 2

This example shows how the `.long` directive initializes words. The symbol `DAT1` points to the first word that is reserved.

```

1 00000000 0000ABCD | DAT1:  .long   0ABCDh, 'A' + 100h, 'g', 'o'
   00000004 00000141 |
   00000008 00000067 |
   0000000c 0000006F |
2 00000010 00000000 |          .long   DAT1, 0AABBCCDDh
   00000014 AABBCCDD |
3 00000018          | DAT2:

```

Example 3

In this example, the `.word` directive is used to initialize words. The symbol `WORDX` points to the first word that is reserved.

```

1 00000000 0000C80 | WORDX:  .word   3200, 1 + 'AB', -0AFh, 'X'
   00000004 00004242 |
   00000008 FFFFFFF51 |
   0000000c 00000058 |

```

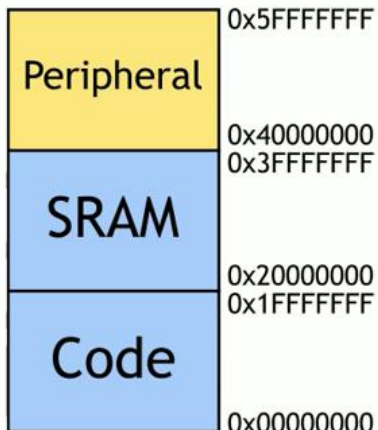

Assembler Directives for Controlling Conditional Computations

Mnemonic and Syntax	Description
.if <i>condition</i>	Assembles code block if the <i>condition</i> is true
.else	Assembles code block if the <i>.if condition</i> is false. When using the <i>.if</i> construct, the <i>.else</i> construct is optional.
.elseif <i>condition</i>	Assembles code block if the <i>.if condition</i> is false and the <i>.elseif</i> condition is true. When using the <i>.if</i> construct, the <i>.elseif</i> construct is optional.
.endif	Ends <i>.if</i> code block
.loop [<i>count</i>]	Begins repeatable assembly of a code block; the loop count is determined by the <i>count</i> .
.break [<i>end condition</i>]	Ends <i>.loop</i> assembly if <i>end condition</i> is true. When using the <i>.loop</i> construct, the <i>.break</i> construct is optional.
.endloop	Ends <i>.loop</i> code block

Example

This example shows conditional assembly:

Memory for Data	Address	Value	Symbol	Operation	Value	
	1	00000001	SYM1	.set	1	
	2	00000002	SYM2	.set	2	
	3	00000003	SYM3	.set	3	
	4	00000004	SYM4	.set	4	
	5					
Memory for Code	6		If_4:	.if	SYM4 = SYM2 * SYM2	
	7	00000000		.byte	SYM4 ; Equal values	
	8			.else		
	9			.byte	SYM2 * SYM2 ; Unequal values	
	10			.endif		
	11					
	12			If_5:	.if	SYM1 <= 10
	13	00000001	0A		.byte	10 ; Less than / equal
	14				.else	
	15				.byte	SYM1 ; Greater than
	16				.endif	
	17					
	18			If_6:	.if	SYM3 * SYM2 != SYM4 + SYM2
	19				.byte	SYM3 * SYM2 ; Unequal value
	20				.else	
	21	00000002	08		.byte	SYM4 + SYM4 ; Equal values
	22				.endif	
	23					
	24			If_7:	.if	SYM1 = SYM2
	25				.byte	SYM1
	26				.elseif	SYM2 + SYM3 = 5
	27	00000003	05		.byte	SYM2 + SYM3
	28				.endif	

Directive for Creating Reusable Block of Codes (i.e. MACRO)

A macro definition is a series of source statements in the following format:

```

macname  .macro  [parameter1 ] [, ... , parametern ]
            model statements or macro directives
            [.mexit]
            .endm
  
```

<i>macname</i>	names the macro. You must place the name in the source statement's label field. Only the first 128 characters of a macro name are significant. The assembler places the macro name in the internal opcode table, replacing any instruction or previous macro definition with the same name.
.macro	is the directive that identifies the source statement as the first line of a macro definition. You must place .macro in the opcode field.
<i>parameter</i> ₁ , <i>parameter</i> _{<i>n</i>}	are optional substitution symbols that appear as operands for the .macro directive.
.mexit	is a directive that functions as a <i>goto .endm</i> . The .mexit directive is useful when error testing confirms that macro expansion fails and completing the rest of the macro is unnecessary.
.endm	is the directive that terminates the macro definition.

Example: $x = a + b + c$

Macro definition: The following code defines a macro, add3, with four parameters:

```

1          *
2
3          *      add3
4          *
5          *      ADDR = P1 + P2 + P3
6
7          add3   .macro P1, P2, P3, ADDR
8
9              ADD    ADDR, P1, P2
10             ADD    ADDR, ADDR, P3
11             .endm
    
```

Create a macro

Macro call: The following code calls the add3 macro with four arguments:

```

12
13 00000000      add3 R1, R2, R3, R0
    
```

Invoke or call a macro

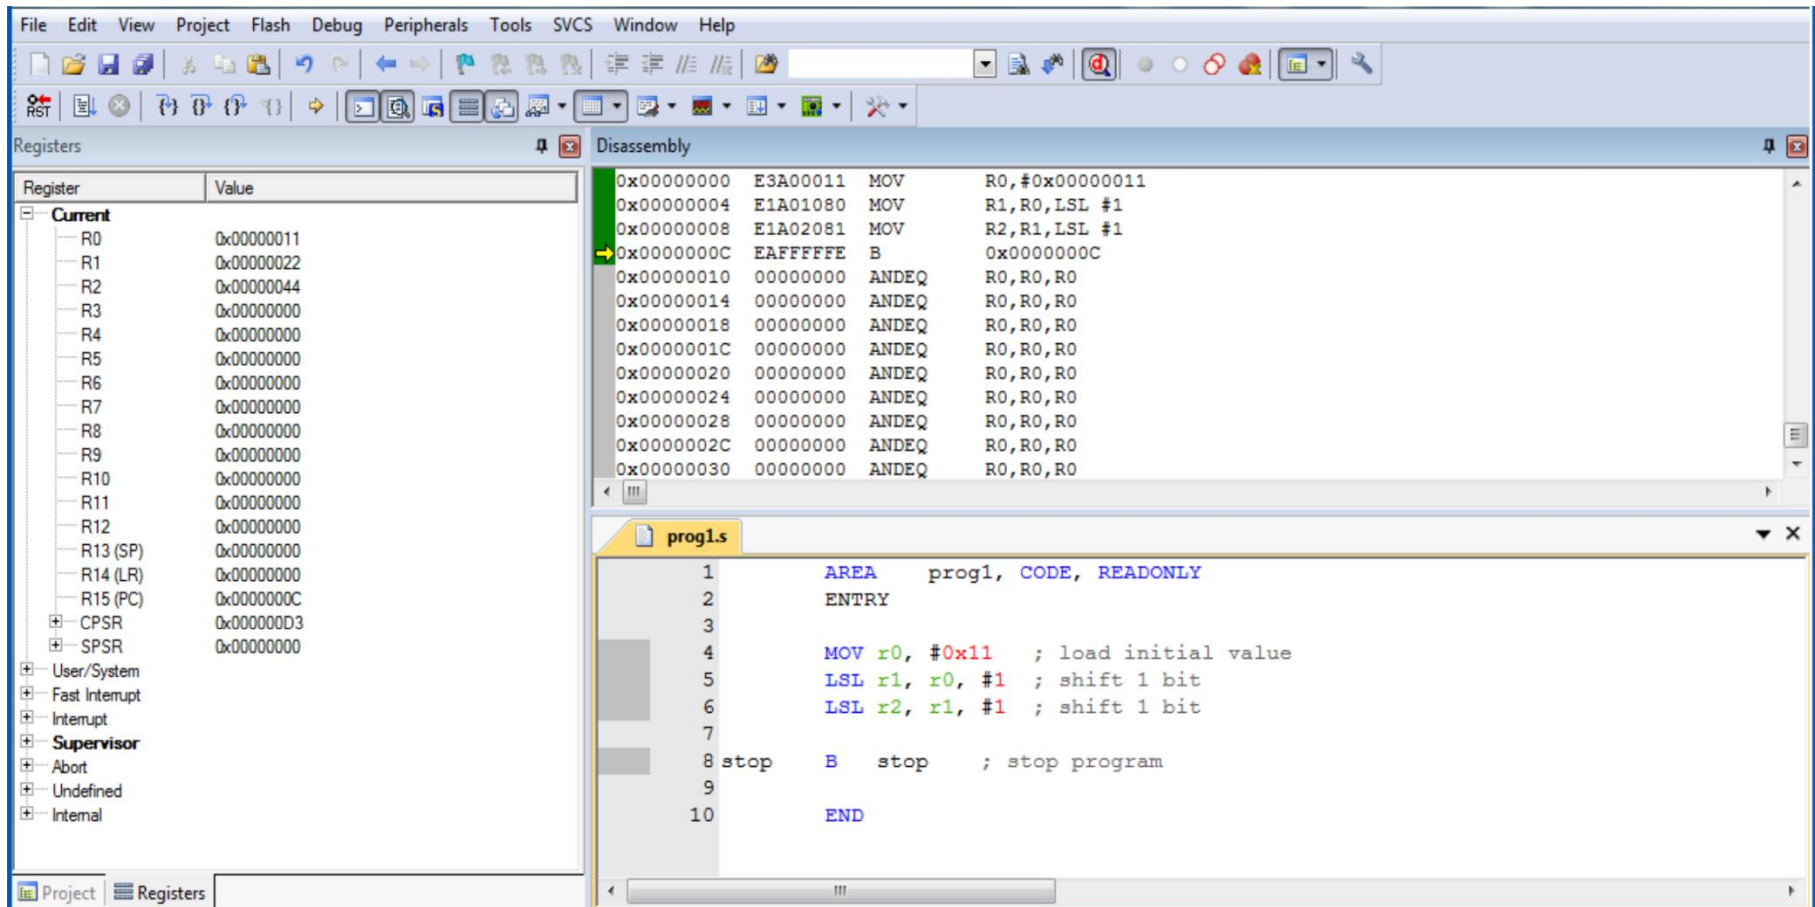

Macro expansion: The following code shows the substitution of the macro definition for the macro call. The assembler substitutes R1, R2, R3, and R0 for the P1, P2, P3, and ADDR parameters of add3.

```

1
1      00000000 E0810002      ADD    R0, R1, R2
1      00000004 E0800003      ADD    R0, R0, R3
    
```

Equivalent instructions

Good News: Integrated Development Environment (Keil)

The screenshot displays the Keil IDE interface with three main windows open:

- Registers Window:** Shows the current state of the processor registers. The R0 register contains the value 0x00000011.
- Disassembly Window:** Shows the assembly code being executed. The current instruction is a Branch (B) instruction at address 0x0000000C, which branches to 0x0000000C.
- Source Code Window (prog1.s):** Shows the assembly source code for the program.

Keil Directives for Allocating Memory to House Instructions/Data

► Format:

{ label } {instruction | directive | pseudo-instruction} { ; comment }

► Example:

Allocating Memory for Code

```

EXPORT Start ; may need to export start
AREA ARMex, CODE, READONLY ; Assembler Directive
; Assembler directive – 1st instruction to
; execute with standalone program
Start MOV r0, #10 ; label & processor instruction
MOV r1, #3 ; another processor instruction
stop B stop ; label & another processor instruction
END ; End of source file – assembler directive

```

Keil Directive for Reusable Instructions (i.e. MACRO and MEND)

- ▶ The MACRO directive marks the start of the definition of a macro. Macro expansion terminates at the MEND directive.

- ▶ Format:

- ▶ MACRO

- ▶ `{ $label } macroname { $cond } { $parameter { , $parameter } ... }`

- ▶ `;` code

- ▶ MEND

- ▶ Example:

```

MACRO
    ; mcro definition
    ; vara=8 * (varb + varc + 6)

$Label_1 AddMul $vara, $varab, $varac

$Label_1
    Add $vara, $varab, $varac
    Add $vara, $vara , #6
    LSL $vara, $vara , #3
MEND
  
```

Invocation of MACRO

MACRO

```
; mcro definition
; vara=8 * (varb + varc + 6)
```

```
$Label_1 AddMul $vara, $varab, $varac
```

```
$Label_1
  Add $vara, $varab, $varac
  Add $vara, $varab, #6
  LSL $vara, $varab, #3
MEND
```

- Invoke Macro

```
      AddMul r0, r1, r2
```
- Resultant code after

```
      ADD r0, r1, r2
      ADD r0, r1, #6
      LSL r0, r1, #3
```

More Example

```

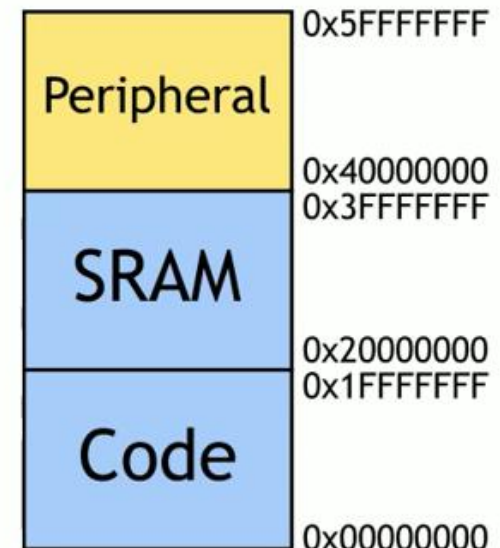

; macro definition
MACRO                                ; start macro definition
$label      xmac      $p1,$p2
            ; code
$label.loop1 ; code
            ; code
            BGE      $label.loop1
$label.loop2 ; code
            BL       $p1
            BGT      $label.loop2
            ; code

```

Allocation of Constants or Parameters in Keil

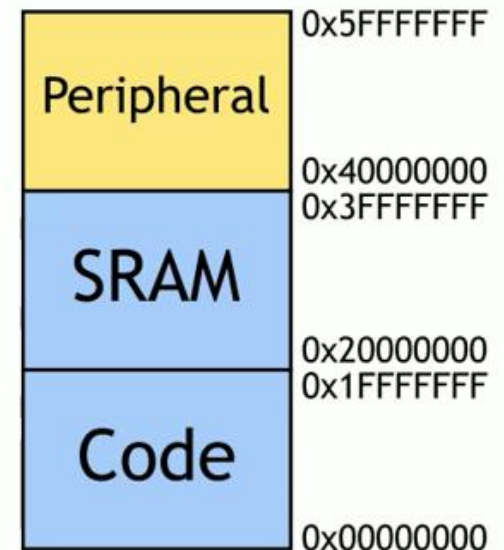

- ▶ Format with SETS Directive:
 - ▶ {name} SETS value
- ▶ Example:
 - ▶ mytext SETS “This is my text” ;
- ▶ Format with EQU Directive:
 - ▶ {name} EQU value {, type}
- ▶ Example:
 - ▶ temperature EQU 25.6 ;

Formats of Numbers in Keil

Number formats

- 123 : decimal number
- 0x3f : hexadecimal number
- n_xxx n : base (2 to 9) , xxx : number
 - 8_12 : octal number 12
- 'A' : single character constant
- "string" : string constants

Frequently Used Keil's Directives

[Assembler User Guide: Directives Reference \(keil.com\)](#)

Keil Directive	Uses
AREA	Defines a block of code or data
RN	Can be used to associate a register with a name
EQU	Equates a symbol to a numeric constant
ENTRY	Declares an entry point to your program
DCB, DCW, DCD	Allocates memory and specifies initial runtime contents
ALIGN	Aligns data or code to a particular memory boundary
SPACE	Reserves a zeroed block of memory of a particular size
LTORG	Assigns the starting point of a literal pool
END	Designates the end of a source file

The END directive informs the assembler that it has reached the end of a source file.

AREA

- ▶ The `AREA` directive instructs the assembler to assemble a new code or data section.

`AREA sectionname {,attr} {, attr}...`

AREA Name, CODE, READONLY

Valid Section Attributes (Keil Tools)

<code>ALIGN = expr</code>	This aligns a section on a 2^{expr} -byte boundary (note that this is different from the <code>ALIGN</code> directive); e.g., if <code>expr = 10</code> , then the section is aligned to a 1KB boundary.
<code>CODE</code>	The section is machine code (<code>READONLY</code> is the default)
<code>DATA</code>	The section is data (<code>READWRITE</code> is the default)
<code>READONLY</code>	The section can be placed in read-only memory (default for sections of <code>CODE</code>)
<code>READWRITE</code>	The section can be placed in read-write memory (default for sections of <code>DATA</code>)

RN Allocation of (Additional) Memory Label

- ▶ The `RN` directive defines a name for a specified register.

- ▶ Format:

`name RN expr`

- *name* – name to assign to the register
- *expr* – takes values between 0 to 15

- ▶ Example:

```
coeff1    RN    8    ; coefficient 1
coeff2    RN    9    ; coefficient 2
dest      RN    0    ; register 0 holds the pointer to
              ; destination matrix
```

EQU

Allocation of Memory Label

- ▶ The `EQU` directive gives a symbolic name to a numeric constant, a register-relative value or a PC-relative value.
- ▶ Format: **Name EQU expr{, type}**
 - *name* is the symbolic name to assign to the value,
 - *expr* is an address or integer constant
 - *Type* is optional and can be: ARM, THUMB, CODE16, CODE32, DATA
- ▶ Example:

```

SRAM_BASE EQU 0x04000000 ; assigns SRAM a base address
abc       EQU 2          ; assigns the value 2 to the symbol abc
xyz       EQU label+8    ; assigns the address (label+8)
                          ; to the symbol xyz
fiq       EQU 0x1C, CODE32 ; assigns the absolute address
                          ; 0x1C to the symbol fiq, and marks it
                          ; as code

```

ENTRY

- ▶ The `ENTRY` directive declares an entry point to a program.

A program must have an entry point. You can specify an entry point in the following ways:

- Using the `ENTRY` directive in assembly language source code.
- Providing a `main()` function in C or C++ source code.

- ▶ Example:

```
AREA  ARMex, CODE, READONLY
ENTRY      ; Entry point for the application.
EXPORT ep1 ; Export the symbol so the linker can find it
ep1       ; in the object file.
          ; code
END
```

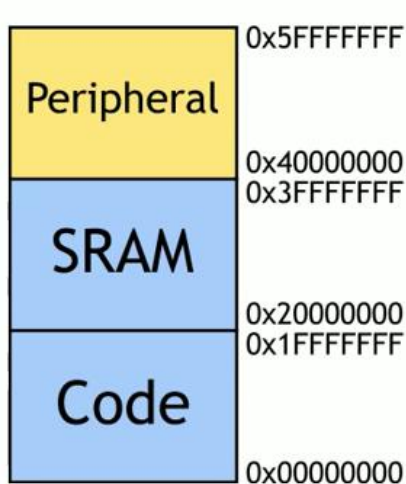

DCB (i.e. Declare 8-bit bytes)

- ▶ The `DCB` directive allocates one or more bytes of memory and defines the initial runtime contents of the memory.

- ▶ Format:

- ▶ {label} DCB expression {, expression} ...

- ▶ Example:

<code>C_string DCB "C_string", 0</code>		Address	ASCII equivalent	
	↖	0x4000	43	C
		0x4001	5F	-
		0x4002	73	s
		0x4003	74	t
		0x4004	72	r
		0x4005	69	i
		0x4006	6E	n
		0x4007	67	g
	↘	0x4008	00	

Last Byte

DCW (i.e. Declare 16-bit words)

- ▶ The `DCW` directive allocates one or more halfwords of memory, aligned on two-byte boundaries, and defines the initial runtime contents of the memory. `DCWU` is the same, except that the memory alignment is arbitrary.

- ▶ Format:

- ▶ `{label} DCW{U} expression {, expression} ...`

- ▶ Example:

```
data    DCW    -225,2*number    ; number must already be defined
        DCWU   number+4
```

DCD (i.e. Declare 32-bit words)

- ▶ The `DCD` directive allocates one or more words of memory, aligned on four-byte boundaries, and defines the initial runtime contents of the memory. `DCDU` is the same, except that the memory alignment is arbitrary.

- ▶ Format:

- ▶ `{label} DCD{U} expression {, expression} ...`

- ▶ Example:

```

data1    DCD      1,5,20      ; Defines 3 words containing
                                ; decimal values 1, 5, and 20
data2    DCD      mem06 + 4   ; Defines 1 word containing 4 +
                                ; the address of the label mem06
                                AREA    MyData, DATA, READWRITE
                                DCB     255      ; Now misaligned ...
data3    DCDU     1,5,20      ; Defines 3 words containing
                                ; 1, 5 and 20, not word aligned

```

ALIGN (i.e. Change offset of alignment)

- ▶ The `ALIGN` directive aligns the current location to a specified boundary.
- ▶ Format: `ALIGN { expr { , offset } }`
expr – a numeric expression evaluating to any power of 2^0 to 2^{31}
*Current location is defined by: offset + n * expr. If not defined, location is the next word.*

▶ Example

```

AREA    cacheable, CODE, ALIGN=3
rout1   ; code           ; aligned on 8-byte boundary
        ; code
MOV     pc,lr  ; aligned only on 4-byte boundary
ALIGN   8      ; now aligned on 8-byte boundary
rout2   ; code

```

```

AREA    OffsetExample, CODE
DCB     1      ; This example places the two bytes in the first
ALIGN   4,3    ; and fourth bytes of the same word.
DCB     1      ; The second DCB is offset by 3 bytes from the
              ; first DCB.

```

ALIGN 4, 3 means: data size = 4 bytes, offset between two consecutive data = 3 bytes

SPACE and FILL (i.e. allocate bytes)

- ▶ The `SPACE` directive reserves a zeroed block of memory. The `FILL` directive reserves a block of memory to fill with a given value.
- ▶ Format:
 - ▶ `{label} SPACE expression`
 - ▶ `{label} FILL expression {, value {, value-size in terms of byte}}`
- ▶ Example:

```
        AREA      MyData, DATA, READWRITE
data1   SPACE    255          ; defines 255 bytes of zeroed store
data2   FILL    50,0xAB,1    ; defines 50 bytes containing 0xAB
```

LTORG (i.e. Lookup-Table Organized)

(Literals mean “fixed and unchanging values”)

- ▶ The LTORG directive instructs the assembler to assemble the current literal pool immediately. The assembler assembles the current literal pool at the end of every code section. The end of a code section is determined by the AREA directive at the beginning of the following section, or the end of the assembly.

In computer science, and specifically in compiler and assembler design, a literal pool is a lookup table used to hold literals during assembly and execution.

The assembler uses **literal pools** to store some constant data in code sections.

- ▶ Example:

Working memory of a function

```

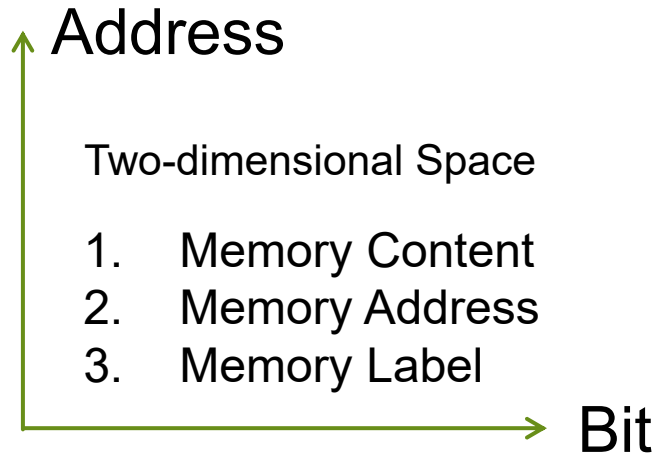

AREA    Example, CODE, READONLY
start  BL      func1
func1                                     ; function body
      ; code
      LDR     r1,=0x55555555 ; => LDR R1, [pc, #offset to Literal Pool 1]
      ; code
      MOV     pc,lr          ; end function
      LTORG                                     ; Literal Pool 1 contains literal &55555555.
data   SPACE  4200          ; Clears 4200 bytes of memory starting at current location.
      END                                     ; Default literal pool is empty.

```

Other Operations Offered by Keil

	Keil Tools
A modulo B	A:MOD:B
Rotate A left by B bits	A:ROL:B
Rotate A right by B bits	A:ROR:B
Shift A left by B bits	A:SHL:B or $A \ll B$
Shift A right by B bits	A:SHR:B or $A \gg B$
Add A to B	$A + B$
Subtract B from A	$A - B$
Bitwise AND of A and B	A:AND:B
Bitwise Exclusive OR of A and B	A:EOR:B
Bitwise OR of A and B	A:OR:B

Summary
